

The last three chapters have focused on specific option contracts on stocks, stock indexes, and interest rate instruments. Where the valuation procedures of Chapters 10 and 11 did not directly apply to these specific option contracts, the procedures were modified. For example, we showed how the quadratic approximation could be used to price American-style index options and how the binomial method could be used to value options on assets with discrete cash flows during the option's life. In this chapter, we discuss options on currencies and on physical commodities. Since no new valuation procedures are needed for these contracts, sections 1 and 2 review only the nature of the exchange-traded options on currencies and physical commodities, and refer the reader to the appropriate valuation equations from the previous chapters. The third section discusses some exotic OTC options that are currently traded. Examples of these are options on options, options on the maximum and the minimum of two risky commodities, lookback options and barrier options. For these four types of options, we present valuation equations. Other types of exotic options include options on the average price of a commodity, deferred-start options, deferred-payment American options, and all-or-nothing options. For these instruments, we describe only the essence of the option contracts. The chapter concludes with a summary.

16.1 CURRENCY AND CURRENCY FUTURES OPTIONS

Option contracts on spot currencies have been actively traded on the Philadelphia Exchange since late 1982. Both European-style and American-style option contracts are traded, with the American-style contracts having the greatest trading volume

and open interest. The most active contracts are for British pounds, German marks, Japanese yen, and Swiss francs, although options on other currencies also trade. Table 16.1 contains a listing of the currently active, exchange-traded currency option contracts. The spot currency must be delivered upon exercise of these options. The current spot prices are also reported in Table 16.1. Currency options expire on the Saturday before the third Wednesday of the contract month.

Valuation of Currency Options

The valuation of currency options is relatively straightforward. First, all of the arbitrage pricing principles developed in Chapter 10 apply. The cost-of-carry rate equals the difference between the domestic interest rate, r_d , and the foreign interest rate, r_f . Second, all of the valuation equations and approximations discussed in Chapter 11 and the trading strategies discussed in Chapter 12 also apply, assuming that the spot exchange rate has a lognormal price distribution at the option's expiration. For

European-style currency options, valuation equations (11.25) and (11.28) can be used, where $b = r_d - r_f$ ¹

For American-style currency options, the quadratic approximation from Chapter 13 is recommended. Again, the cost-of-carry rate is set equal to the difference between the domestic and foreign interest rates.

Option contracts on currency futures were developed in late 1984 and early 1985 by the Chicago Mercantile Exchange. The only such options available are American-style. Upon exercise, a long (call) or short (put) position in the futures is obtained. The expiration date of these options is the second Friday before the third Wednesday of the contract month. (The futures expires two business days before the third Wednesday.) Like the currency options, the most active currency futures options are on British pounds, German marks, Japanese yen, and Swiss francs. Table 16.2 contains current foreign currency futures and futures option contract prices.

The valuation of currency futures options is even more straightforward than the valuation of currency options. The cost-of-carry rate for any currency futures

¹For an approach to foreign currency option valuation that permits interest rates to be stochastic, see Grabbe (1983).

is zero, so we set $b = 0$ in all of the pricing relations of Chapters 10 and 11 and the trading strategies of Chapter 12.

Uses of Currency Options

Currency options are helpful in managing foreign exchange risk that arises in international trade or in the management of international investment portfolios. Currency options allow more flexible hedging of exchange risk than is possible with currency futures alone.

As an example, consider a U.S. importer of German machinery that costs DM500,000 and is to be delivered in March 1992. Payment in German marks is to be made upon delivery. At the March futures price of \$0.6024 shown in Table 16.2, the dollar cost of the machinery will be \$301,200. Of course, if the price of the German mark increases, the dollar cost of the machinery will increase. One way to hedge this exchange risk is to buy four futures contracts (each contract applies to DM125,000) or to enter into an appropriate forward contract with a bank. If the price of the D-mark does increase, the increased equivalent dollar cost of the machinery is offset by the profit on the futures position. On the other hand, if the price of the D-mark decreases, the lower dollar cost is offset by the loss on the futures position.

An alternative way to hedge against D-mark price increases is to buy March call options on the D-mark spot currency or on the D-mark futures. If the D-mark appreciates, the increase in the dollar cost of the machinery is offset by the profit on the call options. On the other hand, if the D-mark depreciates, the lower cost of the machinery is a pure gain. This type of hedge provides insurance against increases in the exchange rate without an offsetting penalty should the exchange rate drop. Naturally, the call premium reflects the value of this insurance. To reduce the premium cost, one might buy out-of-the-money D-mark futures options. For example, Table 16.2 indicates it would have been possible to buy call options on the D-mark futures with an exercise price of 0.61 at a cost of 1.30 cents per mark. Since each contract at the Chicago Mercantile Exchange is DM125,000, four contracts are necessary, and the total premium is \$6,500. This option position would cap the total dollar cost at $(0.61)(500,000) = \$305,000$, while retaining the possibility of gain if the D-mark should depreciate. Increases in the D-mark above 0.61 would be offset by profits on the futures option position.

Options can provide a useful hedge if there is uncertainty about the underlying import or export contract. For example, consider a U.S. company that bids a price of 350,000 pounds to install a computer system in Great Britain and suppose the British company has a month in which to accept or reject the bid. The U.S. company is concerned about a depreciation of the British pound, but if it sells futures to hedge the foreign exchange risk, and the bid is not accepted, the company is left with an open currency futures position that may have to be liquidated at a loss. An alternative hedge is for the U.S. company to buy put contracts on 350,000 British pounds. By purchasing puts, the company guarantees the price at which pounds can be sold if the bid is accepted. If the bid is rejected, the put option is not exercised and is sold. In effect, the U.S. company is using an option to hedge

a contract that has an option feature. The U.S. company has given the British company the put option to sell 350,000 pounds to the U.S. company in return for the computer system. The U.S. company hedges that risk by buying a put.²

In addition to hedging import and export contracts, currency options are useful in international investment and portfolio management. Investment in a foreign country exposes a portfolio to exchange rate risk as well as the usual risk of capital losses. Currency options can be used to modify that risk. For example, an investor in Australian bonds could hedge principal and/or interest payments by purchasing puts on the Australian dollar. Over-the-counter options written by banks are frequently used to tailor such hedges to the needs of the investor, particularly when longer maturities are necessary and/or when a sequence of options is required (as when a stream of coupon payments is hedged). Some fixed-income securities are offered with imbedded currency options. For example, a bond might offer to pay interest and/or principal in either of two currencies at a fixed exchange rate, with the investor having the option to choose the currency. Complex or exotic options, which are discussed below, are often created to deal with currency risk. For example, a bond could offer to pay principal and interest in dollars or in two other currencies at fixed exchange rates established in the bond indenture. The holder of the bond thus has a dollar bond plus the option of choosing the most valuable of the three currencies in which payment may be received.

16.2 PHYSICAL COMMODITY FUTURES OPTIONS

Markets for option contracts on physical commodity futures became active in 1982 with the introduction of sugar futures options by the Coffee, Sugar, and Cocoa Exchange and of gold futures options by the Commodity Exchange. These option contracts are American-style and settle through delivery of a position in the underlying futures. The grain contracts trade predominantly on the Chicago Board of Trade; the livestock contracts on the Chicago Mercantile Exchange; oil and oil-related products on the New York Mercantile Exchange; and metals at the Commodity Exchange. Table 16.3 contains a listing of the currently active, exchange-traded commodity options. As with all futures option contracts, the valuation principles follow from Chapters 10 through 12 once the cost-of-carry rate is set to zero ($b = 0$).

16.3 EXOTIC OPTIONS

Exotic options are complex options that typically incorporate two or more option features. A compound option, for example, is considered an exotic option. It pro-

²The hedging uses of currency options in the kind of situation described here are also discussed in Giddy (1983) and in Feiger and Jacquillat (1979).

vides its holder with the right to buy another option. Options on the maximum of two (or more) risky commodities are also considered to be exotic options. With this option, the investor has the right to buy "the better of two commodities." Because exotic options are complex and are often tailored to the needs of the customer, they are available primarily in the OTC market.

In this section, we apply the lognormal price distribution mechanics used in Chapters 11 and 12 to price compound options (or, more commonly, “options on options”), options on the maximum or the minimum, lookback options, and barrier options. Illustrations are provided. Following these discussions, we describe some other types of exotic options that currently trade. Our list of exotic options is nec-

essarily incomplete, since new option contracts are designed and traded almost every day. The descriptions included will give a flavor for the ingenuity of some current option contract designs.

Options on Options

Compound options or *options on options* fall in the category of exotic options. Call (put) options providing the right to buy (sell) call options (i.e., calls on calls or puts on calls) and call (put) options providing the right to buy (sell) put options (i.e., calls on puts or puts on puts) are the most common forms. To value these options on options,³ we adopt the assumptions and notation used in Chapter 11. The critical assumptions are that the terminal commodity price distribution is log-normal and that the principles of risk-neutral valuation apply. The call and put options that we are valuing are assumed to be European-style with exercise prices, c_t^* and p_t^* , respectively, and with time to expiration t . The notation representing the right to buy a call at time t (i.e., a call on a call) is $c(c,t;c_t^*)$, the right to sell a call at time t (i.e., a put on a call) is $p(c,t;c_t^*)$, the right to buy a put at time t (i.e., a call on a put) is $c(p,t;p_t^*)$, and the right to sell a put at time t (i.e., a put on a put) is $p(p,t;p_t^*)$. The option received or delivered at expiration from the exercise of an option on an option has exercise price X and time to expiration T . The notation used to describe the underlying options is $c(S_t, T; X)$ and $p(S_t, T; X)$, respectively. Conditional upon knowing S_t , these European-style options can be valued using equations (11.25) and (11.28) from Chapter 11.

To demonstrate how to value a compound option, we use a call on a call. The first step in the risk-neutral valuation approach is to formulate the option's payoff contingencies. For the call on a call, the payoff contingencies at time t are

$$c_t = \begin{cases} c(S_t, T; X) - c_t^* & \text{if } c_t > c_t^* \\ 0 & \text{if } c_t \leq c_t^* \end{cases} \quad (16.1)$$

That is, if the value of the call to be received at time t , $c(S_t, T; X)$, is greater than the exercise price, c_t^* , the call option holder will exercise his right to buy the call. If the value is less, he will let it expire worthless.

The second step involves restating the contingent payoffs in (16.1) in terms of the underlying commodity price at time t , S_t , in order to make the problem more

³The models presented in this section are based on the work of Geske (1979).

tractable mathematically. The commodity price above which the call option holder will choose to exercise his call at time t is given by

$$c(S_t^*, T; X) = c_t^*, \quad (16.2)$$

where $c(S_t, T; X)$ represents the European-style option valuation equation (11.25) evaluated at $S = S_t^*$. Note that the value of S_t^* may be solved iteratively in the same manner that we have computed critical commodity prices in earlier chapters.⁴ With S_t^* known, the payoff contingencies expressed in (16.1) may be written as

$$c_t = \begin{cases} c(S_t, T; X) - c_t^* & \text{if } S_t > S_t^* \\ 0 & \text{if } S_t \leq S_t^*. \end{cases} \quad (16.3)$$

Call on Call. Under risk-neutral valuation, the value of a call on a call may be written as the present value of the expected terminal value of the option, where the discount rate is the riskless rate of interest, r :

$$c(c_t, t; c_t^*) = e^{-rt} E[c(S_t, T; X) - c_t^* | S_t > S_t^*] \text{Prob}(S_t > S_t^*). \quad (16.4)$$

Expressing $c(S_t, T; X)$ in terms of its terminal commodity price payoffs and isolating the cost of exercising the option at time t , equation (16.4) becomes

$$\begin{aligned} c(c_t, t; c_t^*) &= e^{-r(t+T)} E(S_T | S_T > X \text{ and } S_t > S_t^*) \text{Prob}(S_T > X \text{ and } S_t > S_t^*) \\ &\quad - e^{-r(t+T)} X \text{Prob}(S_T > X \text{ and } S_t > S_t^*) \\ &\quad - e^{-rt} c_t^* \text{Prob}(S_t > S_t^*). \end{aligned} \quad (16.5)$$

⁴See, for example, the valuation of American-style call options on dividend-paying stocks in Chapter 13 or the valuation of American-style options using the quadratic approximation method in Chapter 14.

Under the assumption that future commodity prices are lognormally distributed, the value of a European-style call on a call is

$$\begin{aligned} c(c_t, t; c_t^*) &= S e^{(b-r)(t+T)} N_2(a_1, b_1; \sqrt{t/(t+T)}) \\ &\quad - X e^{-r(t+T)} N_2(a_2, b_2; \sqrt{t/(t+T)}) \\ &\quad - e^{-rt} c_t^* N_1(b_2), \end{aligned} \quad (16.6)$$

where

$$\begin{aligned} a_1 &= \frac{\ln(S/X) + (b + .5\sigma^2)(t+T)}{\sigma\sqrt{t+T}}, & a_2 &= a_1 - \sigma\sqrt{t+T}, \\ b_1 &= \frac{\ln(S/S_t^*) + (b + .5\sigma^2)t}{\sigma\sqrt{t}}, & b_2 &= b_1 - \sigma\sqrt{t}, \end{aligned}$$

and $N_1(\cdot)$ and $N_2(\cdot)$, are the cumulative univariate and bivariate unit normal density functions described in Chapters 11 and 13, respectively.

In equation (16.6), the term $N_2(a_1, b_1; \sqrt{t/(t+T)})$ is the delta value of the call option on a call option. It describes the call option price movement for a small change in the commodity price. Recall that in Chapter 12 we showed how delta values are used for hedging purposes. The term $N_1(b_2)$ is the probability that the commodity price will exceed the critical commodity price at time t . The term $N_2(a_2, b_2; \sqrt{t/(t+T)})$ is the probability that the commodity price will exceed S_t^* at time t and the exercise price X at time $t+T$.

Put on Call. The simplest way to derive the valuation equation for a put on a call is to deduce the valuation formula from known results. In Chapter 12, we showed that a long-call/short-commodity position is tantamount to a long-put position. Here, the underlying commodity position is a call option, so a long-call-on-a-call/short-call position should be tantamount to a put on a call. Since we have the valuation equation for a call on a call (16.6) and for a European-call (11.25), the valuation equation for a put on a call is

$$\begin{aligned} p(c_t, t; c_t^*) &= S e^{(b-r)(t+T)} N_2(a_1, b_1; \sqrt{t/(t+T)}) \\ &\quad - X e^{-r(t+T)} N_2(a_2, b_2; \sqrt{t/(t+T)}) - e^{-rt} c_t^* N_1(b_2) \\ &\quad - S e^{(b-r)(t+T)} N_1(a_1) + X e^{-r(t+T)} N_1(a_2) + e^{-rt} c_t^* \\ &= X e^{-r(t+T)} N_2(a_2, -b_2; -\sqrt{t/(t+T)}) \\ &\quad - S e^{(b-r)(t+T)} N_2(a_1, -b_1; -\sqrt{t/(t+T)}) \\ &\quad + e^{-rt} c_t^* N_1(-b_2), \end{aligned} \quad (16.7)$$

where all notation is defined in (16.6).

Call on Put. The risk-neutral valuation framework shown above can also be applied to value a call on a put. The value of a *European-style call on a put* is

$$\begin{aligned} c(p_t, t; p_t^*) &= X e^{-r(t+T)} N_2(-a_2, -b_2; \sqrt{t/(t+T)}) \\ &\quad - S e^{(b-r)(t+T)} N_2(-a_1, -b_1; \sqrt{t/(t+T)}) \\ &\quad - e^{-rt} p_t^* N_1(-b_2). \end{aligned} \quad (16.8)$$

The critical commodity price below which the call option holder will choose to exercise the call to buy the put at time t is determined by solving

$$p(S_t^*, T; X) = p_t^*. \quad (16.9)$$

$p(S_t, T; X)$ represents the European-style option valuation equation (11.28) evaluated at $S = S_t^*$. All other notation is as previously defined. The term $N_2(-a_1, -b_1; \sqrt{t/(t+T)})$ is the delta value of a call option on a put option delta value. The term $N_1(-b_2)$ is the probability that the commodity price will be below the critical commodity price at time t . The term $N_2(-a_2, -b_2; \sqrt{t/(t+T)})$ is the probability that the commodity price will be below S_t^* at time t and the exercise price X at time $t + T$.

Put on Put. A put on a put has the same payoff contingencies as a long-call on-a-put/short-put position. Using equations (11.28) and (16.8), it can be shown that the *value of a put on a put* is

$$\begin{aligned} p(p_t, t; p_t^*) &= S e^{(b-r)(t+T)} N_2(-a_1, b_1; -\sqrt{t/(t+T)}) \\ &\quad - X e^{-r(t+T)} N_2(-a_2, b_2; -\sqrt{t/(t+T)}) \\ &\quad + e^{-rt} p_t^* N_1(b_2), \end{aligned} \quad (16.10)$$

where all notation is defined above.

EXAMPLE 16.1

Consider a call option that provides its holder with the right to buy a put option on the S&P 500 index portfolio. The put that would be delivered against the call if the call is exercised has an exercise price of \$400 and a time to expiration of six months. The call has an exercise price of \$10 and a time to expiration of three months. The S&P 500 index is currently at 390, pays dividends at a constant rate of 4 percent annually, and has a volatility rate of 28 percent. The riskless rate of interest is 7 percent.

The first step in valuating the compound option is to compute the critical commodity price below which the call will be exercised to take delivery of the put. This is done by solving

$$p(S_t^*, .5; 400) = 10.00.$$

The critical commodity price, S_t^* , is 497.814. The next step is to apply the valuation formula (16.8). Here, we get

$$\begin{aligned} c = & 400e^{-.07(.25+.5)} N_2(-a_2, -b_2; \sqrt{.25/.75}) \\ & - 390e^{-.03(.25+.5)} N_2(-a_1, -b_1; \sqrt{.25/.75}) \\ & - 10e^{-.07(.25)} N_1(-b_2) = 27.722, \end{aligned}$$

where

$$\begin{aligned} a_1 &= \frac{\ln(390/400) + [.03 + .5(.28)^2](.75)}{.28\sqrt{.75}} = .1096, \\ a_2 &= .1096 - .28\sqrt{.75} = -.1329, \\ b_1 &= \frac{\ln(390/497.814) + [.03 + .5(.28)^2](.25)}{.28\sqrt{.25}} = -1.620, \\ b_2 &= -1.620 - .28\sqrt{.25} = -1.760. \end{aligned}$$

The probability that the commodity price will be below the critical commodity price at time t , $N_1(-b_2)$, is .961. The probability that the commodity price will be below S_t^* at time t and below the exercise price, X , at time $t + T$, $N_2(a_2, b_2; \sqrt{t/(t + T)})$, is .453. The value of a call on a call with the same terms as the put is 27.012. (The critical index price is 342.424.)

Options on the Maximum and the Minimum

Options on the maximum and the minimum of two or more risky commodities are popular exotic options.⁵ For example, someone may buy the right to buy the S&P 500 index or gold for \$400, depending on which commodity is worth more at the option's expiration. As in the case of compound options, options on the maximum and the minimum can be valued straightforwardly, assuming that both commodity prices have lognormal price distributions at the option's expiration. Under the

⁵Other names for the option on the maximum are "the better of two assets" or "outperformance options." The models presented here are on the maximum or the minimum of two risky commodities and the valuation models are based on Stulz (1982). To generalize these models to three or more risky assets, see Johnson (1987).

risk-neutral valuation approach, the value of a call option on the maximum, for example, may be written as

$$\begin{aligned}
 c_{\max}(S_1, S_2; X) = & \\
 & e^{-rT} E(\tilde{S}_{1,T} | S_{1,T} > X \text{ and } S_{1,T} > S_{2,T}) \text{Prob}(S_{1,T} > X \text{ and } S_{1,T} > S_{2,T}) \\
 & + e^{-rT} E(\tilde{S}_{2,T} | S_{2,T} > X \text{ and } S_{2,T} > S_{1,T}) \text{Prob}(S_{2,T} > X \text{ and } S_{2,T} > S_{1,T}) \\
 & - X e^{-rT} \text{Prob}(S_{1,T} > X \text{ or } S_{2,T} > X). \tag{16.11}
 \end{aligned}$$

Under the assumption that future commodity prices are lognormally distributed, the value of a European-style call on the maximum is

$$\begin{aligned}
 c_{\max}(S_1, S_2; X) = & \\
 & S_1 e^{(b_1 - r)T} N_2(d_{11}, d'_1; \rho'_1) + S_2 e^{(b_2 - r)T} N_2(d_{12}, d'_2; \rho'_2) \\
 & - X e^{-rT} [1 - N_2(-d_{21}, -d_{22}; \rho_{12})], \tag{16.12}
 \end{aligned}$$

where

$$d_{11} = \frac{\ln(S_1/X_1) + (b_1 + .5\sigma_1^2)T}{\sigma_1\sqrt{T}}, \quad d_{21} = d_{11} - \sigma_1\sqrt{T},$$

$$d_{12} = \frac{\ln(S_2/X_2) + (b_2 + .5\sigma_2^2)T}{\sigma_2\sqrt{T}}, \quad d_{22} = d_{12} - \sigma_2\sqrt{T},$$

$$d'_1 = \frac{\ln(S_1/S_2) + (b_1 - b_2 + .5\sigma^2)T}{\sigma\sqrt{T}}, \quad d'_2 = -(d'_1 - \sigma\sqrt{T}),$$

$$\sigma^2 = \sigma_1^2 + \sigma_2^2 - 2\rho_{12}\sigma_1\sigma_2, \quad \rho'_1 = \frac{\sigma_1 - \rho_{12}\sigma_2}{\sigma}, \quad \text{and} \quad \rho'_2 = \frac{\sigma_2 - \rho_{12}\sigma_1}{\sigma}.$$

In equation (16.12), the term $1 - N_2(-d_{21}, -d_{22}; \rho_{12})$ is the probability that one of the two commodity prices will exceed the exercise price at time T or, alternatively, one minus the probability that neither commodity will have a price greater than the exercise price at the option's expiration.

EXAMPLE 16.2

Consider a call option that provides its holder the right to buy \$100,000 worth of the S&P 500 index portfolio at an exercise price of \$400 or \$100,000 worth of a particular T-bond at an exercise price of \$100, whichever is worth more at the end of three months. The S&P 500 index is currently priced at \$360, pays dividends at a rate of 4 percent annually, and has a return volatility of 28 percent. The T-bond is currently priced at \$98, pays a coupon yield of 10 percent, and has a return

volatility of 15 percent. The correlation between the rates of return of the S&P 500 and the T-bond is .5. The riskless rate of interest is 7 percent.

Before applying the option on the maximum formula, it is important to recognize that there are two exercise prices in this problem: \$400 for the S&P index portfolio and \$100 for the T-bond. What this implies is that we can buy \$100,000/\$400 = 250 "units" of the index portfolio or \$100,000/\$100 = 1,000 T-bond "units" at the end of three months, depending on which is worth more. At this juncture, we must decide whether to work with the valuation equation (16.12) in units of the S&P 500 index portfolio, in which case we multiply the current T-bond price and its exercise price by 4, and then multiply the computed option price by 250, or to work with the valuation equation (16.12) in units of the T-bond, in which case we divide the current S&P 500 price and the option's S&P 500 exercise price by 4, and then multiply the computed option price by 1,000.⁶ In this exercise, we choose to work in units of the S&P 500 index portfolio, so we adjust the T-bond prices: the current T-bond price is assumed to be 392, and the T-bond exercise price is 400.

With the units of the two underlying assets comparable, we now apply equation (16.12):

$$c_{\max} = 360e^{-.04(.25)}N_2(d_{11}, d'_1; \rho'_1) + 392e^{-.10(.25)}N_2(d_{12}, -d'_2; \rho'_2) - 400e^{-.07(.25)}[1 - N_2(-d_{21}, -d_{22}; .5)] = 11.962,$$

where

$$d_{11} = \frac{\ln(360/400) + [.07 - .04 + .5(.28)^2](.25)}{.28\sqrt{.25}} = -.6290,$$

$$d_{21} = -.6290 - .28\sqrt{.25} = -.7690,$$

$$d_{12} = \frac{\ln(392/400) + [.07 - .10 + .5(.15)^2](.25)}{.15\sqrt{.25}} = -.3319,$$

$$d_{22} = -.3319 - .15\sqrt{.25} = -.4069,$$

$$d'_1 = \frac{\ln(360/392) + [.06 + .5\sigma^2](.25)}{\sigma\sqrt{.25}} = -.5175,$$

$$d'_2 = -(-.5175 - \sigma\sqrt{.25}) = .6388,$$

$$\sigma = \sqrt{.28^2 + .15^2 - 2(.5)(.28)(.15)} = .2427,$$

$$\rho'_1 = \frac{.28 - .5(.15)}{.2427} = .8447,$$

$$\rho'_2 = \frac{.15 - .5(.28)}{.2427} = .0412.$$

⁶These types of adjustments can be made freely because the option price is linearly homogeneous in both the commodity price and the exercise price. See Merton (1973).

The computed option price is 11.962, which implies the value of the option contract is $\$11.962 \times 250$, or $\$2,990.50$. The probability that either or both components of the option are in-the-money at expiration is $1 - N_2(.7690, .4069; .5)$, or 42.72 percent.

Under the same assumptions, the *value of a European-style call on the minimum* is

$$c_{\min}(S_1, S_2; X) = S_1 e^{(b_1 - r)T} N_2(d_{11}, -d'_1; -\rho'_1) + S_2 e^{(b_2 - r)T} N_2(d_{12}, -d'_2; -\rho'_2) - X e^{-rT} N_2(d_{21}, d_{22}; \rho_{12}), \quad (16.13)$$

where all notation is as previously defined.

Lookback Options

Aside from compound options and options on the maximum and the minimum, many other exotic options trade in OTC markets. Some of the options are backward looking. A *lookback call option* provides its holder with settlement proceeds equal to the difference between the highest commodity price during the life of the option less the exercise price, and a *lookback put option* provides its holder with settlement proceeds equal to the difference between the exercise price and the lowest commodity price during the life of the option. It should come as no surprise, therefore, that these options are sometimes referred to as “no-regret options.”

In a sense, lookback options are like American-style options because the option holder is guaranteed the most advantageous exercise price. Lookback call options can be valued analytically using the risk-neutral valuation mechanics.⁷ The reason for this is that it never pays to exercise a lookback option prior to expiration. Independent of how low the commodity price has been thus far during the option's life, there is always some positive probability that it will fall further. For this reason, the option holder will always defer early exercise in the hope of recognizing higher exercise proceeds in the future.

Under the assumptions of risk-neutral valuation and lognormally distributed future commodity prices, the *value of a lookback call* may be written as

$$c_{\text{LB}} = S e^{(b-r)T} N_1(d_1) - X e^{-rT} N_1(d_2) + S e^{(b-r)T} \lambda \left[e^{-b[T + \frac{2 \ln(S/X)}{\sigma^2}]} N_1(d_3) - N_1(-d_1) \right], \quad (16.14)$$

where X is the current minimum price of the commodity during the life of the option, $\lambda = .5\sigma^2/b$, $d_1 = \frac{\ln(S/X) + (b + .5\sigma^2)T}{\sigma\sqrt{T}}$, $d_2 = d_1 - \sigma\sqrt{T}$ and $d_3 = \frac{(b - .5\sigma^2)T}{\sigma\sqrt{T}}$. Note that the first two terms of the option are the value of a European-

⁷The pricing equations provided here are based on the work of Goldman, Sosin, and Gatto (1979).

style call option whose exercise price is the current minimum value of the underlying commodity. This is the least the lookback call can be worth since the commodity price may fall below X , thereby driving the “exercise price” down further.

EXAMPLE 16.3

Consider a lookback call option that provides its holder with the right to buy the S&P 500 index at any time during the next three months. The S&P 500 index is currently at a level of 390, pays dividends at a constant rate of 4 percent annually, and has a volatility rate of 28 percent. The riskless rate of interest is 7 percent.

The cost-of-carry rate is $.07 - .04 = .03$. The value of the lookback call is, therefore,

$$c_{\text{LB}} = 390e^{(.03-.07).25} N_1(d_1) - 390e^{-.07(.25)} N_1(d_2) + 390e^{(.03-.07).25} \lambda \left[e^{-.03[.25 + \frac{2\ln(390/390)}{.28^2}] } N_1(d_3) - N_1(-d_1) \right] = 42.583,$$

where

$$\begin{aligned} \lambda &= .5(.28)^2 / .03 = 1.3067, \\ d_1 &= \frac{\ln(390/390) + [.03 + .5(.28)^2].25}{.28\sqrt{.25}} = .1236, \\ d_2 &= .1236 - .28\sqrt{.25} = -.0164, \end{aligned}$$

and

$$d_3 = \frac{[.03 - .5(.28)^2].25}{.28\sqrt{.25}} = -.0164.$$

Note that the price of the lookback call is considerably higher than an at-the-money index call option. The value of a European-style call (i.e., the sum of the first two terms in the valuation equation) is only 22.941.

The value of a European-style lookback put option is

$$p_{\text{LB}} = Xe^{-rT} N_1(-d_2) - Se^{(b-r)T} N_1(-d_1) + Se^{(b-r)T} \lambda \left[N_1(d_1) - e^{-b[T + \frac{2\ln(S/X)}{\sigma^2}] } N_1(-d_3) \right], \quad (16.15)$$

where all notation is as defined for the lookback call. Note that a standard European-style put option is the lower bound for the price of the lookback put option. The third term is necessarily positive. Using the same parameters as in Example

16.3, the value of a lookback put option is \$43.468, with the underlying ordinary European-style put being valued at \$20.056.

Other backward-looking options are also traded. For example, *average price* or *Asian options* are based on the average (either arithmetic or geometric) commodity price during the option's life. The average commodity price may be used as the exercise price of the option, in which case the settlement value of the call will be the terminal commodity price less the average price, or it may be used as the terminal commodity price, in which case the settlement value will be the average price less the exercise price. Unfortunately, most Asian options do not have closed-form valuation equations. Accurate pricing involves the use of numerical methods.⁸

Barrier Options

Barrier options are options whose existence depends on the underlying commodity price. A *down-and-out call*, for example, is a call that expires if the commodity price falls below a prespecified "out" barrier, H .⁹ At that time, the option buyer may receive a cash rebate, R . A *down-and-in call* is a call that comes into existence if the commodity price falls below the "in" barrier at any time during the option's life. Note that if we buy a down-and-out call and a down-and-in call with the same barrier price, H , exercise price, X , and time to expiration, T , the portfolio has the same payoff contingencies as a standard call option. For this reason, we automatically know how to value a down-and-in call if we can value a down-and-out call.

Under the assumptions of risk-neutral valuation and lognormally distributed commodity prices, the valuation equation for a down-and-out call option is

$$c_{DO} = Se^{(b-r)T} N_1(a_1) - Xe^{-rT} N_1(b_2) - Se^{(b-r)T} (H/S)^{2(\eta+1)} N_1(b_1) + Xe^{-rT} (H/S)^{2\eta} N_1(b_2) + R(H/S)^{\eta+\gamma} N_1(c_1) + R(H/S)^{\eta-\gamma} N_1(c_2), \quad (16.16)$$

H is the barrier commodity price below which the call option life ends; R is the rebate, if any, received by the option buyer should the option terminate,

$$\eta = \frac{b}{\sigma^2} - 1/2, \quad \gamma = \sqrt{\eta^2 + \frac{2r}{\sigma^2}},$$

$$a_1 = \frac{\ln(S/X)}{\sigma\sqrt{T}} + (1 + \eta)\sigma\sqrt{T}, \quad a_2 = a_1 - \sigma\sqrt{T},$$

$$b_1 = \frac{\ln(H^2/SX)}{\sigma\sqrt{T}} + (1 + \eta)\sigma\sqrt{T}, \quad b_2 = b_1 - \sigma\sqrt{T},$$

$$c_1 = \frac{\ln(H/S)}{\sigma\sqrt{T}} + \gamma\sigma\sqrt{T}, \quad \text{and} \quad c_2 = c_1 - 2\gamma\sigma\sqrt{T}.$$

⁸There are a number of useful background readings for those interested in pricing Asian options. Among them are Boyle (1977) and Boyle and Emanuel (1985).

⁹The valuation equation for the down-and-out call option was first provided in Cox and Rubinstein (1985, Ch. 7). The valuation equation presented here is a modified version of the formula presented in Rubinstein (1990).

The valuation equation for a down-and-in call is simply equation (11.25) less (16.16).

EXAMPLE 16.4

Consider a down-and-in call option that provides its holder with the right to buy the S&P 500 index at 380 any time during the next three months, should the index level fall below 375. The S&P 500 index is currently at a level of 390, pays dividends at a constant rate of 4 percent annually, and has a volatility rate of 28 percent. The riskless rate of interest is 7 percent.

The cost-of-carry rate is $.07 - .04 = .03$. The value of the down-and-out call is

$$\begin{aligned} c_{DO} &= 390e^{(.03-.07).25} N_1(a_1) - 380e^{-.07(.25)} N_1(b_2) \\ &\quad - 390e^{(.03-.07).25} (375/390)^{2(\eta+1)} N_1(b_1) \\ &\quad + 380e^{-.07(.25)} (375/390)^{2\eta} N_1(b_2) = 14.817, \end{aligned}$$

where

$$\eta = \frac{.03}{.28^2} - 1/2 = -.1173,$$

$$\gamma = \sqrt{.1173^2 + \frac{2(.07)}{.28^2}} = 1.3414,$$

$$a_1 = \frac{\ln(390/380)}{.28\sqrt{.25}} + (1 - .1173).28\sqrt{.25} = .3091,$$

$$a_2 = a_1 - .28\sqrt{.25} = .1691,$$

$$b_1 = \frac{\ln[375^2/(390 \times 380)]}{.28\sqrt{.25}} + .28(1 - .1173)\sqrt{.25} = -.2512,$$

$$b_2 = b_1 - .28\sqrt{.25} = -.3912,$$

$$c_1 = \frac{\ln(375/390)}{.28\sqrt{.25}} + .28(1.3414)\sqrt{.25} = -.0924,$$

and

$$c_2 = c_1 - .56(1.3414)\sqrt{.25} = -.4680.$$

The value of a standard European-style call option is 28.151, using equation (11.25). The value of the down-and-in call is, therefore, $28.151 - 14.817 = 13.334$.

An *up-and-out put* and an *up-and-in put* can be valued in a similar manner. An up-and-out put is a put that expires if the commodity price rises above the “out” barrier. Its valuation equation is

$$\begin{aligned}
 p_{\text{UO}} = & X e^{-rT} N_1(-b_2) - S e^{(b-r)T} N_1(-a_1) \\
 & + S e^{(b-r)T} (H/S)^{2(\eta+1)} N_1(-b_1) - X e^{-rT} (H/S)^{2\eta} N_1(-b_2) \\
 & - R(H/S)^{\eta+\gamma} N_1(-c_1) - R(H/S)^{\eta-\gamma} N_1(-c_2). \quad (16.17)
 \end{aligned}$$

An up-and-in put comes into existence when the commodity price rises above H . Its valuation equation is simply (11.28) less (16.17).

Other Exotic Options

Exotic options abound.¹⁰ Among those not yet mentioned are those involving deferred features. A *deferred-start option*, for example, is an option which is purchased before its life actually begins. A *deferred payment American option* is like a standard American-style option except, if the option is exercised early, the option buyer does not receive the exercise proceeds until the end of the option’s life. Yet others involve lump sum payoffs. An *all-or-nothing call (put) option*, for example, pays a predetermined amount (i.e., the “all”) should the underlying commodity price be above (below) the exercise price at the option’s expiration. A *one-touch all-or-nothing call (put)* pays a predetermined amount if the commodity price touches the exercise price at any time during the option’s life.

16.4 SUMMARY

This chapter concludes the presentation of option valuation principles and applications. First, we discussed currency and currency futures options. Contract specifications were provided, and we noted that the valuation of these options is a straightforward application of the constant cost-of-carry framework developed in Chapters 10 and 11. The cost-of-carry rate for currency options is the domestic rate of interest less the foreign rate of interest, and the cost-of-carry rate for currency futures options is zero. We discussed, as well, the use of currency options in hedging the currency risk that arises in international trade or investment. Second, we discussed physical commodity futures options. In general, no options on physical commodities trade, only options on physical commodity futures. Hence, the valuation principles for these options also follow straightforwardly from the constant cost-of-carry framework of the earlier chapters. The cost-of-carry rate for physical commodity futures is zero.

¹⁰For a brief review of a range of exotic options, see Hudson (1991).

The remainder of the chapter focuses on exotic options. These are not exchange-traded options but are unusual options that trade in OTC markets. We show how options on options, options on the maximum and the minimum of two commodities, lookback options, and barrier options may be valued within a log-normal price distribution framework. But, these are only four of a myriad of option contract designs that exist in the OTC markets. We discuss others; however, the list is certainly incomplete given the pace with which these new contracts are introduced.
